1 Statement of problem to be solved

Many people around the world use electrical circuits, which require resistors. These resistors have colour codes that allow for the understanding of resistance levels of each resistor. We aim to make it easier to read these resistor values by creating an application that can label a resistor using a camera, allowing the user to simply point the camera and understand the value of that resistor. The value of this project is in the convenience it could provide to everyday hobbyists, along with the accessibility it could provide to people who are colour blind.

2 Stakeholders

The main stakeholders for this application are the development team and our eventual users. However there are a number of different use cases for this application, so we will divide our users into the broad demographics of electronics beginners, colour blind hobbyists, and power users. Beginners are people new to electronics who do not know how to read resistor colour codes and do not yet own a resistance meter to allow for measuring resistance rather than reading it. Another group that has difficulty reading resistor colour codes are colour blind hobbyists. This particular set of people would benefit greatly as without this application they would have to rely on the word from those who are not colour blind, or from the matching of shades. Finally power users who want to quickly find a resistor without manually searching, possibly with other use cases.

3 Contextual Environment

We are targeting the hobbyist electronics market in which axial package resistors with colour band identification is extremely common. In a professional context resistors are mass packaged by resistance making identification trivial. This contrasts greatly with hobbyist electronics where parts are stored with greatly

varying levels of organization, sometimes as poor as a single drawer of loose components of all kinds. Electronics hobbyists must identify components in a wide variety of working environments. Most relevant to our problem is the visual environment as there exists a wide variety of surfaces against which resistors must be identified.
